

AegisOps Demo Script (5 Minutes)

Slide 1 – Introduction (0:00 – 0:30)

"Hello everyone.

Today I'd like to present **AegisOps**, an Autonomous Vendor Outage Investigator built for the AI Accelerator Hackathon 2026.

When a critical vendor such as Stripe, AWS, Cloudflare, or Twilio experiences an outage, Site Reliability Engineers often spend 30 to 90 minutes manually correlating logs, checking status pages, searching the web, notifying teams, creating Jira tickets, and writing postmortems.

AegisOps reduces that process to less than a minute using an intelligent swarm of AI agents orchestrated by LangGraph."

Slide 2 – The Problem (0:30 – 1:00)

"Let's look at the challenge.

Imagine your payment service suddenly starts failing.

Engineers must answer several questions:

- Is this our issue or a vendor issue?
- How severe is it?
- Is there evidence from official status pages?
- Are other customers seeing the same problem?
- What remediation steps should we take?
- How do we communicate the incident?

Today these tasks are mostly manual.

AegisOps automates this entire incident investigation lifecycle."

Slide 3 – High-Level Architecture (1:00 – 1:45)

"AegisOps is powered by an **8-agent LangGraph swarm**.

The workflow begins when logs or monitoring systems detect an anomaly.

The Triage Agent identifies the affected vendor and assigns severity.

Next, the RAG Cache Agent searches historical incidents stored in ChromaDB. If we've seen this issue before and confidence is high, we can skip most of the investigation and immediately move toward remediation.

If the issue is new, the RCA Agent generates hypotheses.

The Browser Agent then checks official vendor status pages using Playwright.

The Web Search Agent validates findings through public sources.

Before any action is recommended, the workflow pauses at a Human-in-the-Loop approval gate.

Once approved, the Remediation Agent proposes containment steps, and finally the Reporter Agent generates a complete postmortem."

Live Demo Begins (1:45 – 2:00)

"Let me show this in action.

I'm going to trigger a simulated Stripe outage scenario."

Run scenario:

```
uv run python backend/main.py --scenario stripe_outage
```

or trigger from the UI.

Slide 4 – Triage & Investigation (2:00 – 3:00)

"As soon as the incident starts, the Triage Agent analyzes incoming logs.

Here we can see it identifies:

- Vendor: Stripe
- Severity: P1
- Impact: Payment processing failures

Immediately after triage, AegisOps creates a Jira ticket and posts a Slack incident notification.

Next, the system checks historical incident memory.

If a matching outage exists with high confidence, the workflow takes a fast path.

Otherwise, the RCA Agent generates possible root causes and decides whether additional investigation is required.

The Browser Agent then visits Stripe's status page automatically and extracts current outage information.

At the same time, the Web Search Agent validates whether the broader community is reporting similar issues."

Slide 5 – Human-in-the-Loop Approval (3:00 – 3:45)

"One important design principle is responsible automation.

Instead of automatically executing remediation, AegisOps pauses at a Human-in-the-Loop checkpoint.

Here the operator reviews:

- Incident summary
- Evidence collected
- Root cause hypotheses
- Recommended actions

Approval can be provided directly from the dashboard or through interactive Slack buttons.

This creates a balance between automation and operational control."

Slide 6 – Remediation & Reporting (3:45 – 4:30)

"Once approved, the Remediation Agent generates containment recommendations.

For example:

- Switch traffic to backup providers
- Enable failover routes
- Notify impacted customers

The Reporter Agent then automatically generates a professional postmortem including:

- Executive summary
- Timeline
- Impact analysis
- Root cause
- Remediation steps
- Long-term recommendations

What traditionally takes engineers hours can now be completed in seconds."

Closing & Impact (4:30 – 5:00)

"To summarize:

AegisOps combines LangGraph orchestration, RAG memory, browser automation, web intelligence, Slack integration, Jira automation, and human oversight into a single autonomous incident response platform.

The result is:

- Faster incident triage
- Reduced mean time to resolution
- Consistent postmortems
- Improved operational efficiency
- Continuous learning through incident memory

Thank you for your time.

I'd be happy to answer any questions."
